

# Programming Massively Parallel Processors

## A Hands-on Approach

### CHAPTER 14 (PART 1) > Sparse Matrix Computation

A **dense matrix** is one where the majority of elements are not zero

A **sparse matrix** is one where many elements are zero

(many real world systems are sparse)

- Opportunities:

- Do not need to allocate space for zeros (save memory capacity)
- Do not need to load zeros (save memory bandwidth)
- Do not need to compute with zeros (save computation time)

- Many storage formats for sparse matrices:
  - Coordinate Format (COO)
  - Compressed Sparse Row (CSR)
  - ELLPACK Format (ELL)
  - Jagged Diagonal Storage (JDS)
  - ...
- Format design considerations:
  - Space efficiency (memory consumed)
  - Flexibility (ease of adding/reordering elements)
  - Accessibility (ease of finding desired data)
  - Memory access pattern (enabling coalescing)
  - Load balance (minimizing control divergence)

- Choice of best format depends on computation
- We will use **Sparse Matrix-Vector multiplication** (SpMV) as an example to study different formats

Matrix:

|   |   |   |   |
|---|---|---|---|
| 1 | 7 |   |   |
| 5 |   | 3 | 9 |
|   | 2 | 8 |   |
|   |   |   | 6 |

Store every nonzero  
along with its row  
index and column  
index

Row:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 0 | 0 | 1 | 1 | 1 | 2 | 2 | 3 |
|---|---|---|---|---|---|---|---|

Column:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 2 | 3 | 1 | 2 | 3 |
|---|---|---|---|---|---|---|---|

Value:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 7 | 5 | 3 | 9 | 2 | 8 | 6 |
|---|---|---|---|---|---|---|---|

Matrix:

Multiple threads  
writing to the same  
output  
(need atomic  
operations)

Row:

Column:

Value:

**Parallelization  
approach:**

Assign one thread per  
nonzero

```
__global__ void spmv_coo_kernel(COOMatrix cooMatrix, float* inVector, float* outVector) {  
    unsigned int i = blockIdx.x*blockDim.x + threadIdx.x;  
    if(i < cooMatrix.numNonzeros) {  
        unsigned int row = cooMatrix.rowIdxs[i];  
        unsigned int col = cooMatrix.colIdxs[i];  
        float value = cooMatrix.values[i];  
        atomicAdd(&outVector[row], inVector[col]*value);  
    }  
}
```

- Advantages:
  - Flexibility: easy to add new elements to the matrix, nonzeros can be stored in any order
  - Accessibility: given nonzero, easy to find row and column
  - SpMV/COO has coalesced memory accesses
  - SpMV/COO has no control divergence
- Disadvantage:
  - Accessibility: given a row or column, hard to find all nonzeros (need to search)
  - SpMV/COO uses atomic operations

Matrix:

|   |   |   |   |
|---|---|---|---|
| 1 | 7 |   |   |
| 5 |   | 3 | 9 |
|   | 2 | 8 |   |
|   |   |   | 6 |

Store nonzeros of  
the same row  
adjacently and an  
index to the first  
element of each row

RowPtrs:

|   |   |   |   |   |
|---|---|---|---|---|
| 0 | 2 | 5 | 7 | 8 |
|---|---|---|---|---|

Column:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 2 | 3 | 1 | 2 | 3 |
|---|---|---|---|---|---|---|---|

Value:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 7 | 5 | 3 | 9 | 2 | 8 | 6 |
|---|---|---|---|---|---|---|---|

Matrix:

## Parallelization approach:

Assign one thread to loop over each input row sequentially and update corresponding output element

RowPtrs:

Column:

Value:

Matrix:

## Parallelization approach:

Assign one thread to loop over each input row sequentially and update corresponding output element

RowPtrs:

Column:

Value:

Matrix:

## Parallelization approach:

Assign one thread to loop over each input row sequentially and update corresponding output element

RowPtrs:

Column:

Value:

```
__global__ void spmv_csr_kernel(CSRMatrix csrMatrix, float* inVector, float* outVector) {
    unsigned int row = blockIdx.x*blockDim.x + threadIdx.x;
    if(row < csrMatrix.numRows) {
        float sum = 0.0f;
        for(unsigned int i = csrMatrix.rowPtrs[row]; i < csrMatrix.rowPtrs[row + 1]; ++i) {
            unsigned int col = csrMatrix.colIdxs[i];
            float value = csrMatrix.values[i];
            sum += inVector[col]*value;
        }
        outVector[row] = sum;
    }
}
```

- Advantages:
  - Space efficiency: row pointers smaller than row indexes
  - Accessibility: given a row, easy to find all nonzeros
  - SpMV/CSR avoids atomics, every thread owns its output
- Disadvantage:
  - Flexibility: hard to add new elements to the matrix
  - Accessibility: given nonzero, hard to find row; given a column, hard to find all nonzeros
  - SpMV/CSR memory accesses are not coalesced
  - SpMV/CSR has control divergence

Matrix:

|   |   |   |   |
|---|---|---|---|
| 1 | 7 |   |   |
| 5 |   | 3 | 9 |
|   | 2 | 8 |   |
|   |   |   | 6 |

Like CSR, but groups  
nonzeros by column

(useful for computations other  
than SpMV that require column  
traversal, such as SpMSpV)

ColPtrs:

|   |   |   |   |   |
|---|---|---|---|---|
| 0 | 2 | 4 | 6 | 8 |
|---|---|---|---|---|

Row:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 0 | 1 | 0 | 2 | 1 | 2 | 1 | 3 |
|---|---|---|---|---|---|---|---|

Value:

|   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|
| 1 | 5 | 7 | 2 | 3 | 8 | 9 | 6 |
|---|---|---|---|---|---|---|---|
